antibody array; breast milk; food allergens; food allergy.

Abstract

Food allergy is recognized as a major public health issue, especially in early childhood. It has been hypothesized that early sensitization to food allergens maybe due to their ingestion as components dissolved in the milk during the breastfeeding, explaining reaction to a food, which has never been taken before. Thus, the aim of this work has been to detect the presence of the food allergens in breast milk by microarray technology. We produced a homemade microarray with antibodies produced against major food allergens. The antibody microarray was incubated with breast milk from 14 women collected from Fundación Jiménez Díaz Hospital. In this way, we demonstrated the presence of major foods allergens in breast milk. The analysis of allergens presented in breast milk could be a useful tool in allergy prevention and could provide us a key data on the role of this feeding in tolerance induction or sensitization in children.

Food allergy is recognized as major public health issue, and its prevalence has been increasing over the last years (1). The incidence of food allergy is especially serious in early childhood. Except for milk, egg, and peanut, no treatment has been described at present and nowadays, strict avoidance of allergen-containing foods is the way to avoid these allergic reactions. It has been hypothesized that early sensitization to food allergens is probably due to their ingestion as components dissolved in the milk during the breastfeeding. However, only peanut, egg, and milk allergens have been described in breast milk (2–4). To our knowledge, the limited number of allergens detected in breast milk is more likely a technical problem that a scarce presence of allergens and so,

other allergens has not been detected in breast milk. This work attempts to explain why a child has an allergic reaction to a food which has never eaten before or that the adverse reactions to breast milk during lactation could be due to the presence of these allergens.

In this work, we have developed an antibody array to detect different food allergens and we studied their presence in breast milk samples. Microarray technology is a sensitive relevant technique in the allergy field that allows us testing simultaneously multiple allergens. We selected ten major food allergens from the most frequent allergenic foods, some of them, panallergens [such as lipid transfer protein (nsLTP), profilin, thaumatin, or parvalbumin], to have a wide range available. Positive results could explain the sensitization during the breastfeeding to other foods, such as nuts or fruits that can subsequently trigger cross-reactivity.

Antibodies were purchased or produced in our laboratory using purified allergens (Table 1). Rabbit antisera were

produced following the technique described by Albar et al. (5). Ovalbumin was provided by Sigma. Sin a 2, Pru p 3, Pru p 2, Cit la 2, and Tri a 14 were purified as previously described (6).

Microarrays were printed by Raybiotech (Norcross, GA, USA) that provides us all reagents. Thirty-five microliters from samples were biotinylated according to manufacture protocol. The glass slide containing arrays was incubated for 1 h at room temperature with blocking solution (provided by Raybiotech), and the biotin-labeled reagent was added onto the glass slide, which is preprinted with capture antibodies, and incubated overnight at 4°C to allow for the interaction of target proteins. After washing, streptavidin-conjugated fluorescent dye (Cy3 equivalent) is then added to the array and incubated for two hours at room temperature. Finally, the

glass slide is dried, and laser fluorescence scanning is used to visualize the signals, that was digitized with Axon Genepix 4200A Professional (Molecular Devices, Sunnyvale, CA, U.S.A.) and analyzed with GenePix™ software (Molecular Devices, Sunnyvale, CA, USA). Only those spots having two replicates fulfilling the analysis criteria and provided that signals are well above background (Mean background + 3 standard deviation, accuracy \approx 95%) were considered for analysis. Fluorescence units (FU) were defined as mean signal intensity for spot minus mean signal intensity for background.

We checked the selectivity and sensitivity of microarrays using decreasing amount of purified allergens or allergic food. Antibody microarray were able to detect nanograms of each allergen checked (Fig. S1). Breast milk from 14 women was collected from Fundación Jiménez Díaz Hospital (Madrid,

Figure 1 Detection of allergens in breast milk samples by antibody microarray. Measures were normalized to the amount of protein; Normalized fluorescence unit = Fluorescence Unit/mg protein loaded in the array.

Spain), and protein content was quantified. The study was approved by the hospital ethics committee, and all women gave their written consent to participate in the study. Milk samples were analyzed showing the presence of different allergens. Due to the wide variation of protein concentration in the different breast milks, ranging from 30 to 70 mg/ml, results were normalized to the amount of protein (FU/mg protein loaded in the array). Interestingly, as internal selectivity control, the amount of cow milk allergens varied in the different samples, without detecting these allergens in some human breast milks. Unspecific signals in milk allergens should be in all samples if microarray could recognize human caseins instead of Bos d 8. Nevertheless, it is shown in Fig. 1, the normalized FU measure for milk allergens is low in several samples, being undetectable in a sample (BM9). Therefore, these data provide the high selectivity of the antibody array.

Antibody array was able to detect all allergens studied (Fig. 1). Some proteins such as profilins, thaumatins, or ovalbumin, although degraded by gastric enzymes, have been detected in breast milk by polyclonal antibodies (3). In these cases, protein proteolysis could render peptides or protein fragments, large enough to be recognized by polyclonal antibodies. The high number of allergens detected and the great variety between the different samples might be due to the content of allergens depends on several factors: the mother diet or the allergen structure features as the intrinsic resistance to proteolytic degradation. Also, the sensitization to allergens with a high structural stability and present in much consumed foods during the breastfeeding could explain the episodes of allergy to foods previously never eaten by the child.

Human milk is a complex substance that contains, among others, antibodies (mainly secretory immunoglobulin A), antioxidants, fatty acids, lactoferrin, hormones, growth factors, anti- and pro-inflammatory cytokines, and nutrients (7). The benefits of breastfeeding are widely accepted as it can promote stimulation of the immune system and the correct development of gut mucosal barrier (8, 9). But there is still lot of debate regarding on human milk constituents and its role in the development of allergic disease. Thus, some factors in human milk have been described with protective effects against atopy (10–12), while others increase the risk of atopy and subsequent allergy development (13–16).

We demonstrated the presence of allergens in breast milk probably due to the food ingestion from the mother diet. In this sense, a common practice has been to recommend mothers

to avoid the ‘allergenic foods’ from their diet during lactation as a preventive measure (17). Although in 1994, Canadian Task Force on the Periodic Health Examination suggested that dietary measure results are unsuccessful due to the variation on amount of antigens in breast milk, data confirmed by us with the antibody microarrays assay (Fig. 1). Although inflammatory responses or tolerance induction of the newborn depends on more factors as, for instance, the immaturity of the intestinal barrier (18), the analysis of allergens in breast milk could be a useful tool in allergy prevention. A study with an increasing number of allergens and quantifying their concentration, as well as following the development of allergic diseases in the children that have taken these breast milks, could provide key data on the role of this feeding in tolerance induction or sensitization in children.
